Campaign for selling personal loans

This case is about a bank (Thera Bank) which has a growing customer base. Majority of these customers are liability customers (depositors) with varying size of deposits. The number of customers who are also borrowers (asset customers) is quite small, and the bank is interested in expanding this base rapidly to bring in more loan business and in the process, earn more through interest on loans. In particular, the management wants to explore ways of converting its liability customers to personal loan customers (while retaining them as depositors). A campaign that the bank ran last year for liability customers showed a healthy conversion rate of over 9% success. This has encouraged the retail marketing department to devise campaigns with better target marketing to increase the success ratio with minimal budget.

The department wants to build a model that will help them identify the potential customers who have a higher probability of purchasing the loan. This will increase the success ratio while at the same time reduce the cost of the campaign.

The file Bank.xls contains data on 5000 customers. The data include customer demographic information (age, income, etc.), the customer's relationship with the bank (mortgage, securities account, etc.), and the customer response to the last personal loan campaign (Personal Loan). Among these 5000 customers, only 480 (= 9.6%) accepted the personal loan that was offered to them in the earlier campaign.

1. Import required libraries and read the dataset. (2 points)
2. Check shape and info of the dataset. (3 points)
3. Use describe function to get summary of data and mention your findings (5 points)
4. Study the data distribution in each attribute, share your findings. (5 points)
5. Get the target column distribution and mention your comments. (3 points)
6. Do bivariate analysis and mention your inferences (Hint - you can use pairplot) (5 points)

7. Take absolute values of experience for further analysis. (3 points)
8. Split the data into training and test set in the ratio of 70:30 respectively. (2 points)
9. Build a Logistic Regression model to predict the likelihood of a liability customer buying personal loans (10 points)
10. Print the confusion matrix for the model (5 points)
11. Print model score for both train and test data. (4 points)
12. Print classification report. (3 points)
